

Slackware ARM current gcc-10.3.x armv8 arm64 aarch64 cross-compiler for the Raspberry Pi 4

Preface

With the recent updates on [Slackware ARM](#) (December 2020) to gcc-10.x this is an ARMv8 aarch64 cross-compiler bash script that's intended for building binaries from source code and turning them into Slackware packages. Or whatever use you may find for this script.

Previous [work in this area](#) had been done for gcc-9.x and the build script and instructions are mostly the same. Some of the code in the script has changed from the old version, with updated versions and especially the patching.

Notes

Slackware ARM current was used on a Raspberry Pi 4 [4GB RAM] to build and install the gcc-10.3.0 aarch64-linux cross-compiler.

The Linux kernel source downloaded is from the Raspberry Pi Github repository:
<https://github.com/raspberrypi/linux>

For usage see the commented section at the top of the script itself. It explains pretty much everything you need to know in order to get started and be successful. If you need to you can refer to the instructions on [this page](#) as they are exactly the same, apart from the version numbers.

NB: 'libsanitizer asan' will need patching before building glibc. The issue itself is that no PATH_MAX has been defined in the source and there needs to be a value set in order for it to compile successfully. The patching is all done by the script code. No user input is required after running it.

Requirements

As a pre-requisite, you should have;

- a Raspberry Pi 3 or 4 (i.e. a 64bit CPU) running Slackware ARM current with as much unused [\geq 5GB] storage space on your system as possible.
- [gawk](#), [git](#), [bison](#) and [flex](#), already installed on your system.

Aarch64 cross-compiler script code

Download the 'SARPi64.SlackBuild-gcc-10.3-aarch64-cc.sh' file by clicking the link at the top of the

script code (or copy and paste the code if you prefer) below.

Make the file executable using 'chmod +x SARPi64.SlackBuild-gcc-10.3-aarch64-cc.sh' or 'chmod 755 SARPi64.SlackBuild-gcc-10.3-aarch64-cc.sh' command.

Refer to the commented top section of the script code for usage.

[SARPi64.SlackBuild-gcc-10.3-aarch64-cc.sh](#)

```
#!/bin/bash

# 2016-12-05 by Exaga - v0.1a - alpha
#
#####
#####
#
# This script downloads RPi Linux kernel source and the required
# binaries,
# and configures, builds, patches, and installs a gcc 10.3.x aarch64-
# linux
# cross-compiler on Slackware ARM current running on a Raspberry Pi
# 3/4.
#
### Usage & Installation ###
# You should create a 'build-dir' folder and copy this script to it
# (e.g. /tmp/build-dir) and run it from there as a 'root' user.
#
# ~# chmod +x SARPi64.SlackBuild-gcc-10.3-aarch64-cc.sh
# ~# ./SARPi64.SlackBuild-gcc-10.3-aarch64-cc.sh
#
# You may install the cross-compiler anywhere you like, as long as it
# can be
# accessed by a normal user (i.e. not 'root'). The default is
# /tmp/.gcc-cross
# but if this is not suitable then set your own installation directory
# with
# INSTALL_PATH variable, in the settings below.
#
# Ensure 'bison', 'flex', 'gawk', and 'git' are installed on your
```

```
system
# before running this script! Use these commands to check:
#
# ~# whereis gawk
# ~# whereis git
# ~# whereis bison
# ~# whereis flex
#
# If you need to install any of the packages above [* check for
updates!]:
#
http://slackware.uk/slackwarearm/slackwarearm-current/slackware/a/gawk\*
.txz
#
http://slackware.uk/slackwarearm/slackwarearm-current/slackware/d/git\*
.txz
#
http://slackware.uk/slackwarearm/slackwarearm-current/slackware/d/bison
*.txz
#
http://slackware.uk/slackwarearm/slackwarearm-current/slackware/d/flex\*
.txz
#
# NB: The gcc package you compile should match your currently installed
gcc
# version. Use this command to check your current gcc version:
#
# ~# gcc --version
#
# More recent gcc packages-versions may exist. You may wish to install
them.
# NB: if you use newer packages - glibc version MUST suit gcc
version! The
# thing to make sure is the release dates of gcc and glibc versions
being as
# close as possible.
#
# binutils - https://ftp.gnu.org/gnu/binutils/
# cloog - ftp://gcc.gnu.org/pub/gcc/infrastructure/
# gcc - https://ftp.gnu.org/gnu/gcc/
# glibc - https://ftp.gnu.org/gnu/glibc/
# gmp - https://ftp.gnu.org/gnu/gmp/
# isl - ftp://gcc.gnu.org/pub/gcc/infrastructure/
# mpfr - https://ftp.gnu.org/gnu/mpfr/
# mpc - https://ftp.gnu.org/gnu/mpc/
#
### IMPORTANT! ###
# This script will export the INSTALL_PATH variable into the $PATH.
# The PATH of the cross-compiler should always be the first item in
# the $PATH. PATH command:
#
```

```
# ~# export PATH=/tmp/.gcc-cross/bin:$PATH
#
# To check that the INSTALL_PATH is in your $PATH use this command:
#
# ~# echo $PATH
#
### Usage ###
# This script was created on Slackware ARM and intended for research
and
# development towards a Slackware AArch64 port. This script may work on
# other Linux distributions and hardware but it has not been tested and
# therefore cannot be verified. It may be freely distributed, copied,
# modified, or plagiarised in the hope that it will be of some use
towards
# the goal of Slackware AArch64.

Configuring the system to use the Aarch64 cross-compiler

Once the cross-compiler has been built and you intend to use it to compile Aarch64 [64bit] binaries, the location of the tool-chains must be exported to your system's \$PATH variable. It's also prudent to have this entry appear before all other PATHs. So, for example, to check what your existing \$PATH includes, use the 'echo \$PATH' command like this:

```
root@slackware:~# echo $PATH
/usr/local/sbin:/usr/sbin:/sbin:/usr/local/bin:/usr/bin:/bin:/usr/games:/usr
/lib/qt/bin
```

This is the output of the \$PATH on our Slackware ARM system before adding the '/path/to/cross-compiler/bin' tool-chain location. Your own \$PATH might be very different.

If you didn't change the 'INSTALL_PATH' variable in the build script then the command the script uses to export the PATH will be like this:

```
root@slackware:~# export PATH=/tmp/.gcc-cross/bin:$PATH
```

This is the command to use if it doesn't already appear in your system \$PATH. Obviously, if you've modified the INSTALL_PATH variable then that location will be used instead of the default. You can check the \$PATH variable to ensure that it has been added correctly:

```
root@slackware:~# echo $PATH
/tmp/.gcc-
cross/bin:/usr/local/sbin:/usr/sbin:/sbin:/usr/local/bin:/usr/bin:/bin:/usr/
games:/usr/lib/qt/bin
```

The example output above all looks good because the cross compile PATH appears first before everything else.

Aarch64 cross-compiling 'HOWTO' example

So, when the Aarch64 tool-chains feature in the \$PATH on the system, they can be utilised to build software for the ARMv8 architecture instead of your Slackware ARM system's [ARMv7] existing infrastructure. It's all done via the 'make' process.

As an example to show how this can be achieved, the bespoke RPi kernel source 'master' branch will be used. This kernel source will be downloaded and located in '/tmp/linux-rpi' directory. **[NB: note that this is NOT '/usr/src/linux' - it should never reside in that standard location for cross-compiling purposes!]**. After downloading the Linux source, use 'cd' to the directory where it's located:

```
root@slackware:~# git clone --depth=1 git://github.com/raspberrypi/linux
/tmp/linux-rpi
Cloning into '/tmp/linux-rpi'...
~ Enumerating, Counting, Compressing, yadda yadda yadda ~
Updating files: 100% (66403/66403), done.
root@slackware:~# cd /tmp/linux-rpi/
root@slackware:/tmp/linux-rpi#
```

We use '-depth=1' option to only download the latest commit and not the entire branch content, which may currently be +10GB in size. The actual disk space amount used for the source that's just been downloaded is:

```
root@slackware:/tmp/linux-rpi# du -sh /tmp/linux-rpi/
```

1.2G /tmp/linux-rpi/

To verify which major/minor revision of the Linux kernel source you're working with, use the 'head' command on the 'Makefile', like this:

```
root@slackware:/tmp/linux-rpi# head -5 Makefile
# SPDX-License-Identifier: GPL-2.0
VERSION = 5
PATCHLEVEL = 4
SUBLEVEL = 83
EXTRAVERSION =
root@slackware:/tmp/linux-rpi#
```

At the time of writing, this is kernel 5.4.83 source from the Raspberry Pi Github repository 'master' branch. You can download and work with other branches by simply manipulating the 'git' command options. Right now the downloaded kernel source is in a "raw state" (i.e. it includes no settings or configurations) and it's not going to build anything until some form of instructions exist regarding specifically how/what/which to compile.

What's missing now is a kernel '.config' - a file that includes instructions (i.e. settings) that's an essential prerequisite in order to compile the Linux source into a resulting kernel image file - and you won't be doing much without creating one first. This is much easier said than done if you're starting from scratch, because it requires intimate knowledge about the the computer/device hardware that you're building the kernel to support. However, with the Raspberry Pis (and many other ARM devices) there is such a thing as a 'default config', or 'defconfig', that can be called to build the kernel '.config' file for you and save a lot of time and effort (and unfortunately a huge amount of education and experience is also wasted in this process). So in the interest of saving time, let's do it the easy and lazy way for this example...

For the Raspberry Pi 3 to build a default kernel '.config' file for Aarch64 architecture:

```
root@slackware:/tmp/linux-rpi# make ARCH=arm64 CROSS_COMPILE=aarch64-linux-
bcm2709_defconfig
```

For the Raspberry Pi 4 to build a default kernel '.config' file for Aarch64 architecture:

```
root@slackware:/tmp/linux-rpi# make ARCH=arm64 CROSS_COMPILE=aarch64-linux-
bcm2711_defconfig
```

OK! So, normally you would just use 'make <deviceId>_defconfig' to achieve this but here it's the 'ARCH=arm64 CROSS_COMPILE=aarch64-linux-' that makes ALL the difference. You should now have a '.config' file in your Linux source directory which reflects that. Check it out with the 'head' command:

```
root@slackware:/tmp/linux-rpi# head -10 .config
#
# Automatically generated file; DO NOT EDIT.
# Linux/arm64 5.4.83 Kernel Configuration
```

```
#  
  
#  
# Compiler: aarch64-linux-gcc (GCC) 10.3.0  
#  
CONFIG_CC_IS_GCC=y  
CONFIG_GCC_VERSION=100300  
root@slackware:/tmp/linux-rpi#
```

If this is what you see then it's perfect and ready to compile your kernel. In exactly the same way, now 'make' the kernel image, BUT... invoke 'multijobs' as well. Multijobs is the '-j4' option. The '-j<number>' will use more than just a single core of the CPU to build and dramatically cut down on the compile time(s) involved. The RPi3 and RPi4 have quad-core CPUs so it's quite safe to use four cores here, like this:

```
root@slackware:/tmp/linux-rpi# make -j4 ARCH=arm64 CROSS_COMPILE=aarch64-  
linux- Image
```

Incidentally, and very logically, it's the same structure and options to compile the DTBs, kernel-headers, modules, etc. and install them:

```
root@slackware:/tmp/linux-rpi# make -j4 ARCH=arm64 CROSS_COMPILE=aarch64-  
linux- dtbs
```

```
root@slackware:/tmp/linux-rpi# make -j4 ARCH=arm64 CROSS_COMPILE=aarch64-  
linux- headers_install
```

```
root@slackware:/tmp/linux-rpi# make -j4 ARCH=arm64 CROSS_COMPILE=aarch64-  
linux- modules
```

```
root@slackware:/tmp/linux-rpi# make -j4 ARCH=arm64 CROSS_COMPILE=aarch64-  
linux- modules_install
```

NB: Under normal circumstances you wouldn't compile and install the kernel-headers (as they are already included in the kernel) unless you're intending to build external modules or "outside of source-tree" software. If you don't understand what this means or what it entails, then skip the kernel-headers completely.

BEFORE CONTINUING - Make a back-up FIRST of your '/boot/' directory before coping any new files to it, in case things don't go exactly as planned. Only reboot once everything is correctly in place and you have your backup(s) to fall-back on.

So with everything compiled and built, you just need to copy the 'kernel' image, 'DTBs' and 'System.map' to your '/boot' directory.

NB: By default, on Raspberry Pi ARMv7 [32-bit] systems, the kernel image is named 'kernel7.img' on the RPi3, and for the RPi4 the kernel image is named 'kernel7l.img' -

where the "L" is actually an indicator for "Large Physical Address Extension (LPAE)". However, on Raspberry Pi ARMv8 [64-bit] systems the kernel is named 'kernel8.img'. This filename MUST be correct in order for the boot-loader to find and run the ARMv8 [64-bit] kernel! If you have specified a custom kernel image filename in the

'/boot/config.txt' file then you already know what you're doing here.

```
root@slackware:/tmp/linux-rpi# cp -avr arch/arm64/boot/Image  
/boot/kernel8.img"  
root@slackware:/tmp/linux-rpi# cp -avr  
arch/arm64/boot/dts/broadcom/bcm27*.dtb /boot/  
root@slackware:/tmp/linux-rpi# cp -avr System.map /boot/System.map
```

That's it! When you reboot your system it should now be using a 64bit kernel and modules. One should be mindful that [Slackware Aarch64](#) is in development and building kernels using a cross-compiler will soon become superfluous on that system architecture, but for 32bit systems and users a cross-compiler may still be relevant.

I hope this Aarch64 cross-compiler build script and/or information will be useful for Slackware [ARM] users in whatever ways are possible. Any questions or assistance can be addressed via the [Linux Questions forum\(s\)](#)

Thanks very much for your interest in this Aarch64 cross-compiler on the Raspberry Pi.
